HW1

(2: Ch#1 Ex#1)

 $\ensuremath{\mathbf{False}}$ Consider the following example:

m ranks women as: w > w'm' ranks women as: w' > ww ranks men as: m' > mw' ranks men as: m > m'

In such a case there is no possible stable matching where the men m or m' can be paired up with their top preferences.

(3: Ch#1 Ex#2)

True Consider the statement to be false. In that case m pairs up with woman w' such that $w' \neq w$ and hence w pairs up with m' such that $m' \neq m$. Now preference wise m is ranked at the top for w and vice-versa(in on of the instances, preferences do not change with instances). So given that the pairs in this instance are (m, w') and (m', w) man m would have preferred w' over w and w would have preferred m' over m. But this contradicts the fact that m and w are at the top of each other's list.

(4)

False Consider this case:

 $\begin{array}{l} m \longrightarrow w > w' \\ m' \longrightarrow w' > w \\ w \longrightarrow m' > m \\ w' \longrightarrow m > m' \end{array}$

There is one possible pairing: (m, w); (m', w') if men propose. However if women propose (m', w); (m, w') is also one possible configuration. So the G - S algorithm still gives **unique** solutions if **only men** or **only women** propose. So even though the male and female versions produce two independent outputs, the output from either of them is still unique!

(5)

A stable matching will not always exist. Consider the case of simple cyclic permutations: $a \longrightarrow b > c > d$

 $b \longrightarrow c > d > a$ $c \longrightarrow d > a > b$

 $d \longrightarrow a > b > c$

They cannot settle down with their first choices since (a, b); (c, d) is unstable as b prefers c to be its room mate and d prefers a followed by b to be its roommate.

(6: Ch#1, Ex#3)

Let the n shows of A have a rating given by $\{A_1, A_2, ..., A_n\}$ and that of B have $\{B_1, B_2, ..., B_n\}$. Consider a simpler case A_1, A_2, A_3 , and B_1, B_2, B_3 such that $A = \{1, 3, 5\}$ and $B = \{2, 4, 6\}$ would result in a configuration as B, B, A and if however B now changes it configuration to $\{4, 2, 6\}$ the new configuration would be $\{B, A, B\}$ clearly violating the requirements of stability.

(7: Ch#1, Ex#4)

while there is a hospital $h \in H$ with atleast one spot empty that hasn't been offered to $s \in E$ do hire the next best valid student s' as in the preference list of h if s' free then s' gets hired by h, number of open spots reduce by 1 else if s' ranks h higher to its current employer h' then s' leaves h'; h becomes occupied; h' has 1 less student else s' remains with originla h' and h is still free and moves on to the next student on its preference list end end end To prove it's correctness: First type of instability: s is assigned h, s' is assigned no hospital and h prefers s': Let as assume First type of stability exists. Since h prefers s', it must have tried to hire s' before it hired s, but s' could have refused since there was another hospital h'' which was higher ranked than s' But at the end s' lands up with no hospital which is a CONTRADICTION. Second Type of instability: s assigned h; s' assigned h', h prefers s' to s and s' prefers h to h'. Let us assume such an instability exists. Since h prefers s to s', it must have tried to hire s' at some point to which s' refused leading to hire of s or alternative s' was hired but later on wasa asked by another hospital h'' which was higher on its preference list leading to s' leaving h, But now it is with h' which is lower ranked than h which is clearly a CONTRADICTION since s' is supposed to be	Let H represent the set of hospitals and S represent the set of students

After stable matching terminated man m1 changed his mind to marry woman w2 though he was already married to w1 Original preference list : w1 > w2 New preference list: w2 > w1 Let the original pairing be (m1, w1) and (m2, w2). New pairings : ?

Case1: If w2 prefers m2 over w1 the change in preference of m1 does not matter, as even if he now asks w2 he would be refused since she is already engaged with a person ranked higher.

Case2: If w2 prefers m1 over m2 and now m1 also prefers w2 over m1, then when it is m1's turn he would ask w2 instead of w1 and stands a chance to get engaged initially(when w2 divorves m2) Now m2 is free, w1 is free and the G-S algorithm starts to run again with m2. m2 will not start from the top of his list but should make an efficient choice to start from where he was left off by w2, because he is going to go further down the ladder(he would be rejected again by all women who were above w2 in his list even if he chososes to ask them again) so he 'initiates' the 'G-S' by asking a woman w' who was ranked just below to w2. The procedure then otherwise continues like normal G-S, though w1 is free and would get engaged as soon as m2 or any other person proposes her.
